ABSTRACT

In this article, estimates of the cost of raising a child, that are available from the U.S. Department of Agriculture, are described: the most widely requested estimates updated to current price levels are provided: and the most frequently asked questions about the use and interpretation of these estimates are answered. Information on additional materials of interest to users of the estimates are also described. Tables are provided on the annual cost of raising an urban child from birth to age 18, in different regions and economic levels (economy, low, and moderate cost) for the years 1960-1979: food plans drawn up according to family size and income for 1978: and consumer price index data for updating and backdating cost estimates of child rearing. (SS)

Reproductions supplied by EDPS are the best that can be made from the original document.

# USERS' GUIDE TO USDA ESTIMATES OF THE COST OF RAISING A CHILD

By Carolyn S. Edwards<sup>1</sup>

\ Estimates of the cost of raising a child, developed in the Family Economics Research Group of the U.S. Department of Agriculture (USDA), have received a great deal of attention. These figures have been used not only as a budgetary aid for individual families as original, ly intended, but have been applied in legal, social welfare, educational, and research situations as well. The estimates have been used, for example, to provide guidelines for judges, attorneys, and expert witnesses in setting support payments for children in divorce cases (25) and in estimating damages arising from personal injury, wrongful death, and malpractice claims. They have been applied by State, county, and municipal social welfare agencies in setting public support levels for families and children, and by educators, financial advisers, and other professionals who work with families or who train those who will. Researchers have used the estimates in analyses on particular family situations, fertility behavior, and other demographic and population topics (23, 24, 26, 28, 29). The estimates have also been quoted widely in newspapers and popular publications.

This interest and diversity of uses, however, has generated numerous questions and some confusion with regard to what estimates are available and how they may be used. This article describes what estimates are available, provides the most widely requested estimates updated to current price levels, answers the most frequently asked questions about their use and interpretation, and describes information on additional materials of interest to users of the estimates.

# **AVAILABLE ESTIMATES**

The cost estimates of raising a child were developed as a result of two separate but

<sup>1</sup> Economist, Family Economics Research Group, Science and Education Administration, USDA, related research efforts. In both, total and annual costs from birth to age 18 were determined for eight items in the budget: Food at home, food away from home, housing, transportation, medical care, education, clothing, and all other items. The estimates do not include costs for the birth of the child or for higher education.

The first of the studies (3, 4, 5, 6) was based on data from the 1960-61 Consumer Expenditure Survey (CES), a cooperative project of the USDA and the U.S. Department of Labor, Bureau of Labor Statistics (BLS). Estimates reflected average expenditure patterns of families with husband and wife present and with no more than five children. Costs were developed separately for families living in the North Central, Northeast, South, and West and for those living in urban, rural farm, and rural honfarm settings. The estimates were developed at three cost levels-economy, low, and moderate. Table 1 shows cost estimates for raising urban Children in each of the four regions, updated to 1978 price levels.<sup>2</sup>

The second study (1), based on data from the 1973 Farm Family Living Expenditure Survey (FFLES) and on procedures modified from the first study, provides new estimates of the cost of raising farm children. Unlike the earlier estimates, these are not limited to families of a particular type or size, nor are they specific to regions. The estimates provide costs by sex as well as age of the child at four cost levels—thrifty (similar to the economy level), low, moderate, and liberal. These estimates, updated to 1977 price levels, were printed in the Winter 1979 issue of FAMILY ECONOMICS REVIEW.

e estimates.

<sup>&</sup>lt;sup>2</sup> Estimates from this study for rural nonfarm children, updated to 1978 price levels, are available from the Pamily Economics Research Group (see page 2 of this issue for address).

# USE AND INTERPRETATION3

The estimates are expressed in terms of average costs for a child at a given age. They are based on families with children at those ages and take into account the needs, expenditure patterns, and family characteristics related to the age of the child. Estimates for children in specific circumstances, for example, children in foster care and in single-parent families, are not available; neither are estimates specific to birth order or spacing of children. A part of the first study that focused on the costs of raising children in families of different sizes indicated that the cost differences between 2- and 3-child families ranged from 7 to 12 percent (5). Cost differences between 3- and 4-child families also ranged from 7 to 12 percent. Costs per child decreased only 4 or 5 percent between 4- and 5-child families. A complete set of estimates specific to family size, however, has not been developed.

Most of the data on expenditures were reported in terms of the family unit in which the child lived. These expenditures had to be allocated to reflect each family member's share. To the extent possible, the allocation methods took into account both the portion of family expenditures which is related to family size and accompanying economies of scale and the portion which is attributable to individual family members based on their age and sex. For example, although per person housing and transportation costs do not increase directly in proportion to family size, these costs are more influenced by family size than by the age and sex of the family member. Per person food and clothing costs, on the other hand, are more nearly related to physiological and social needs that are tied to age and sex. Although there are some economies of scale in feeding larger families, there is not much savings associated with an increase in family size.

The estimates place emphasis on direct costs, or out-of-pocket expenditures, and therefore,

The information in this section is general and applicable to the estimates from both studies. Users should realize, however, that although a similar overall approach was applied to both data bases (2), changes in data collection, variable definition, and estimation procedures were inevitable and, in some cases, desirable. The estimates from the two studies are therefore not directly comparable. Users needing more specific detail should refer to the original papers (1, 4), available from the Family Economics Research Group.

do not represent the total consumption costs involved in raising a child. For example, they generally do not reflect family consumption that might be attributed to stocks of durables, past expenditures, income-in-kind, gifts, or the value of community services. Similarly, no account is made for the value of personal services performed by family members or earnings given up while raising children.

The CES and the FFLES provide cross-section data that present a detailed picture of the spending patterns of the population at one point in time—the early sixties for the urban and rural nonfarm estimates, and the early seventies for the farm estimates. The cost figures from birth to age 18 as presented in table 1, therefore, do not reflect the change in level and mix of goods and services available to or consumed by one household as a result of changes in prices, income, or preferences experienced as the child grows up. Instead, the estimates represent the experience and behavior of different families with dildren at various ages and expenditure patterns prevalent at the time the data were collected.

#### Cost Levels

The levels of the estimates are based on, spending patterns associated with food consumption at the levels of the USDA food plans (7, 9). The families whose expenditures formed the basis of the estimates reported food expenditures equal to the food plan costs. Estimates for clothing at the low cost level, for example, were based on clothing expenditures of families whose food expenditures corresponded to the low cost food plan for families of their size and composition.

This use of the food plans as a benchmark for the cost levels of the estimates assumes that families who are spending at similar cost levels on food, allowing for differences in family size and composition, are living at similar levels. These levels are, in turn, reflected in other areas of consumption. An advantage of this approach is that food is the one category of consumption, for which standards of adequacy are available. Use of the food plans also allows differences in family size and composition to be taken into consideration, which is not possible with income, the more common indicator of level of living.

FAMILY ECONOMICS REVIEW

Users of the estimates often ask which cost level they should use and how these levels relate to family income. Table 2 may be used to help select the appropriate cost level (8). This table is designed for use in conjunction with the food plans, however, and provides only general guidance for selecting child rearing cost estimates. The relationships indicated in the table were developed on a different data base, using different methods than the estimates of the cost of raising a child.

# Region and Urbanization

The estimates developed in the first study were specific to region and to urbanization. The four regions were those used by the U.S. Bureau of the Census, and include these States:

North-Central	Northeast
Illinois	Connecticut "
Indiana	• •
Iova	Maine
Kansas	Massachusetts
Michigan .	New Hampshire
Minnesota - /	New Jersey
Missouri	New York
Nebraska	Pennsylvania
North Dakota	Rhode Island
Oh to •	Vermont
South Dakota	·
Wisconsin	
•Sout h	West
Alabama	Artzona
Arkansas	California
Florida	Colorado
Georgia	Ldaho
Kentucky	Mont ana
Louisians	
Maryland	New Mexico
Mississippi	Oregon '
North Carplina	Utah
Oklahoma (	<ul> <li>Washington</li> </ul>
South Carolina	Wyoming
Tennessee .	
Texas	
Virginia	
West Virginia	•
Delaware	•

Alaska and Hawaii were not represented. The District of Columbia was included, in the South. Estimates for a U.S. average were not developed in the first study. If such an indicator is necessary, use of the estimates for the North Central region is most appropriate.

The definition of urbanization used in the CES data and reflected in the estimates from the first study included urban, rural nonfarm, and rural farm. Urban included incorporated places of a population of 2,500 or more or the

densely settled areas immediately adjacent to cities of a population of 50,000 or more. Rural nonfarm included those areas outside urban areas but not classified as farm. To be a rural farm, a 10-acre parcel needed sales of at least \$50 per year; a parcel of less than 10 acres needed sales of at least \$250. This definition of farmayas also used in the FFLES data base.

# Price Level Adjustments

Users may wish to make adjustments to the price levels so that the estimates will suit their particular needs. The estimates may be updated or backdated using appropriate subindexes of the Consumer Price Index provided in table 3. Each budget category must be adjusted individually to reflect differential price-level changes between budget items over time.

Before adjusting the price levels, users should determine whether constant or current dollar figures are more suitable to their needs. The estimates in table 1 are expressed in constant 1978 dollars and assume that the child progresses through '18 years at 1978 price levels. Constant dollar estimates are appropriate when interest is with the present costs of raising children of different ages. They are not appropriate for determining the total cost of raising one child; they are too high for the child who reaches age 18 in 1978, and too low for the child born in 1978.

·When concern is with past or future costs of raising an individual child or a cohort of children of a particular age, however, current dollar estimates that reflect prices actually incurred should be used. Current dollar estimates may be calculated by applying price indexes for the different budget items for the calendar year corresponding to the child's age (table 3) to the cost estimates for that age (table 1). For example, the current dollar estimates to raise a child born in 1960 in the urban South at the moderate cost level would be \$37,061 (table 4) compared with the constant 1978 dollar estimates of \$60,298 (table 1). This current dollar estimate was calculated by applying the 1960 indexes to the estimated casts of the infancy year, the 1961 indexes to the age 1 estimates, and so on for the remaining years and adding to arrive at the total. Such a figure could be calculated to estimate past costs incurred raising a particular child born in 1960. If concern were with projecting costs

**SUMMER 1979** 

over the life of a child, as in anticipating support costs to be incurred for a particular child, users would want to consider projections for future price changes. For example, for a child born in 1976, the 1978 annual cost estimates for the infancy year could be backdated by use of the 1976 indexes, the annual figures for age 1 could be adjusted by use of the 1977 indexes, the figures for age 2 could be taken as is for 1978, and cost estimates for subsequent ages could be inflated sequentially by use of some projected price change assumptions for future years. A total could then be reached that would reflect the experienced and expected price changes over the life of the child as well as the cost changes associated with growth of the child.

Consideration also could be made for changes in family level of living over the life cycle by combining figures at different cost levels. For example, it might be assumed that a child was raised for several years at one cost level and for other years at another.

# ADDITIONAL MATERIALS RELATED TO THE COST OF RAISING A CHILD

Users of the child rearing cost estimates often inquire about additional materials to aid in the use and interpretation of the figures. The following materials provide supplementary detail on particular items in the budget, or extend the use of the estimates to other topics.

## USDA Budgets for Food and Clothing

The child rearing estimates are cost budgets. They do not provide information on the quantity or quality of items actually purchased or needed to attain a given cost level or standard of adequacy. The USDA budgets for food and clothing, however, provide this information at comparable cost levels.

The food budgets (plans) take into account current information on nutritional needs and food consumption patterns as well as the nutrient content and prices of food. The food plans specify the amounts of food in 11 food groups needed to provide nutritionally adequate diets to persons in 20 age-sex groups at four cost levels—thrifty, low, moderate, and liberal (7, 9). A plan for any family can be determined by adding amounts of foods suggested for persons of the sex and age of family members (8). The

costs of the plans for the U.S. average are released monthly and published quarterly in FAMILY ECONOMICS REVIEW. Costs specific to the four regions are published in the Summer issue of FAMILY ECONOMICS REVIEW.

Cost and quantity budgets for clothing were developed by the USDA in two studies based on the same data used for the cost of raising a child estimates. The 1960-61 CES data provided estimates of the annual costs of clothing purchases for 21 categories of individuals, based on age, sex, and marital and employment status, and by urbanization, region, and cost level (10, 11, '13). The 1973 FFLES data provided the basis for annual cost estimates for farm children and adults for six clothing cate: gories (15, 16). Estimates for farm children were published in the Winter 1979 issue of FAMILY ECONOMICS REVIEW; estimates for adults are on page 17 of this issue. Clothing quantity budgets (12) and an Interactive Computer Program for Wardrobe Replacement Planning (14) were also developed using the 1960-61 CES.

# **Higher Education**

Costs for higher education are not included in the child rearing cost estimates. Estimates of the costs of tuition, fees, and room and board rates for institutions of higher education are available from the National Center for Education Statistics, U.S. Department of Health, Education, and Welfare (17). Estimates for the 1978-79 academic year indicate that such costs, per academic year, range from about \$1,800 to \$2,350 for public institutions and from about \$3,470 to \$5,610 for private, depending on the type of institution-2-year, 4-year, or university. Detail is also available on costs by type of charge, control and type of institution, and by residence status of the student. Another annual publication from the same agency provides estimated cost figures for the 1963-64 through 1976-77 academic years and projections of estimated charges at three cost levels for the 1977-78 through 1986-87 academic years in constant 1976-77 dollars (18).

#### Cost of Having a Baby

The child rearing cost estimates also do not include the costs involved in having a baby. As

FAMILY ECONOMICS REVIEW

recent release from the Health Insurance Institute (27) estimates this cost to be about \$2,170 to \$2,220. This estimate includes \$888 for hospital care, \$518-568 for medical care, and \$762 for the layette. (This last figure includes \$397 for nursery furnishings, identified as optional.) Costs for maternity clothes and unusual expenses such as drugs were not included. Data sources for the report were survey's conducted by the Health Insurance Association of America, MEDICAL ECO-NOMICS, the Children's Bureau of the U.S. Department of Health, Education, and Welfare, the Health Insurance Institute, and materials from a children's clothing manufacturer.

# **Bureau of Labor Statistics Family Budgets**

Standard budgets are also published by the U.S. Department of Labor's Bureau of Labor Statistics. These budgets cover all the outlays ( of other sizes and composition (21).

made by a family (20, 22). They are designed to represent the costs of hypothetical lists of goods and services specified to portray three relative levels of living-lower, intermediate, and higher. The budget costs are periodically priced for 39 urban areas (19).

The USDA estimates differ from the BLS budgets in that the USDA estimates focus on specific expenditure categories. They reflect the spending patterns of actual families at specified cost levels, rather than a specified list of goods and services as in the BLS budgets. In addition, the USDA estimates focus on individuals of different age and sex living in urban, rural farm, and rural nonfarm families. The BLS budgets represent a precisely specified urban family of four: A husband age 38, his unemployed wife, a girl age 8) and a boy age 13. An equivalence scale may be used with the BLS budgets to estimate the costs for families

The Revised Consumer Price Index for urban wage earners and clerical workers (CPI-W) replaced the unrevised CPI; use revised as shown for adjusting estimates to 1978 and on; unrevised CPI for adjusting to 1953-1977; monthly indexes are seasonally adjusted.

<sup>2</sup>In using the revised CPI-W to adjust estimates of the cost of raising a child (table 1), the "Personal and educational expenses" index should replace the "Reading and recreation" index; the average of the "Personal care" and the "Personal and educational expenses" indexes should replace the average of the "Personal care" and the "Reading and recreation" indexes.

Source: U.S. Department of Labor, Bureau of Labor Statistics.

Note: To adjust the price levels of the estimates of the cost of raising a child to specific year price of levels, multiply the 1978 estimate for each budget category by the index number for that category for the desired year and divide the product by the corresponding index number for 1978. For example, in order to update 1978 costs for housing to March 1979 prices, multiply the 1978 estimate for housing by 217.5 and divide by 202.6. In order to backdate 1978 costs for housing to 1968 prices, multiply the 1978 estimate for housing by 104.2 and divide by 202.6.

Table 4. Cost of raising a child born in 1960 in the urban South at the moderate cost level; prices are current for each year specified
